

A QCNN for Quantum State Preparation

Carnegie Vacation Scholarship

David Amorim

Week 6
(05/08/2024 - 14/08/2024)

Erratum

The slides for the previous weeks showed the wrong placement of the absolute signs in the definition of SAM. The definition should read:

$$\text{SAM}(|x\rangle, |y\rangle) = 1 - \sum_k |x_k| |y_k|. \quad (1)$$

This has now been corrected. Equivalently for WIM.

Aims for the Week

The following aims were set at the last meeting (05/08/2024):

Generalise Input States

When training in superposition, feed in a wider range of input states to ensure the network learns as intended.

Work on Code and Documentation

Continue re-structuring and re-documenting the code to ensure a smooth handover.

TRY AND DO SOME BARREN PLATEAU ???

Table of Contents

① Generalised Input States

② Code and Documentation

③ Next Steps

Generalised Input States

- When training in superposition, the QCNN now takes the input state

$$|\psi\rangle_{\text{in}} = \sum_{j=0}^{2^n-1} c_j |j\rangle \quad (2)$$

where the **coefficients** $c_j \sim \frac{1}{\sqrt{2^n}}$ are **randomly sampled** each epoch

- The **range** of the random sampling is controlled by a **hyper-parameter** δ , $0 \leq \delta \leq 1$
- For instance, $\delta = 0$ gives $c_j = \frac{1}{\sqrt{2^n}}$ while $\delta = 1$ gives $c_j \in (0, 1)$
- This generalisation should ensure that the network learns the operation $|j\rangle |0\rangle \mapsto |j\rangle |\Psi'(j)\rangle$ as opposed to just learning how to produce a particular fixed state

Results

Amplitudes after applying \tilde{Q} with $\Psi(f) \sim f^2$ and the input register in initial state $\hat{H} |0\rangle$ ($L = 6$, $m = 3$, SAM, 600 epochs):

Figure 1: $\delta = 0$

Figure 2: $\delta = 0.2$

Results

Amplitudes after applying \tilde{Q} with $\Psi(f) \sim f^2$ and the input register in initial state $\hat{H} |0\rangle$ ($L = 6$, $m = 3$, SAM, 600 epochs):

Figure 3: $\delta = 0.4$

Figure 4: $\delta = 0.6$

Results

Amplitudes after applying \tilde{Q} with $\Psi(f) \sim f^2$ and the input register in initial state $\hat{H} |0\rangle$ ($L = 6$, $m = 3$, SAM, 600 epochs):

Figure 5: $\delta = 0.8$

Figure 6: $\delta = 1.0$

Results

- It seems that randomised input states ($\delta \neq 0$) actually have an **adverse effect** on performance
- Notably, increasing δ leads to **thin 'stripes'** in the amplitude plots, i.e. sudden changes in amplitude between neighbouring states
- This could suggest a structural **defect in input layer design**

Notably, there is a 'stripey' texture...
also, try playing around with control
state

Figure 7: Comparing the effect of δ values for $\Psi(f) \sim f^2$ ($L = 6$, $m = 3$, SAM, 600 epochs)

Table of Contents

- ① Generalised Input States
- ② Code and Documentation
- ③ Next Steps

Code and Documentation

- Continued work on code documentation: now hosted online [here](#)

TO DO:

- a write doc strings for `testQNN`, `trainQNN`, `ampl_trainQNN`
- b make sure to update doc files on github (-o /docs)
- c add plotting into comman-line feature (re-write `plotting_tools` and `check_plots ...`)
- d integrate `encode.py`

Table of Contents

- ① Generalised Input States
- ② Code and Documentation
- ③ Next Steps

Next Steps

- Start work on poster for Carnegie
