David Amorim PQC Function Evaluation 2024

## Background

• Hayes 2023¹ presents a scheme to encode a complex vector  ${m h}=\{\tilde A_j e^{i\Psi(j)}|0\leq j< N\}$  as the state

$$|h\rangle = \frac{1}{|\tilde{A}|} \sum_{j=0}^{2^{n}-1} \tilde{A}(j) e^{i\Psi(j)} |j\rangle, \qquad (1)$$

using  $n = \lceil \log_2 N \rceil$  qubits

ullet This requires operators  $\hat{U}_A$  and  $\hat{U}_\Psi$  such that

$$\hat{U}_A |0\rangle^{\otimes n} = \frac{1}{|\tilde{A}|} \sum_{j=0}^{2^{n-1}} \tilde{A}(j) |j\rangle, \qquad (2)$$

$$\hat{U}_{\Psi} |j\rangle = e^{i\Psi(j)} |j\rangle \tag{3}$$

David Amorim PQC Function Evaluation

<sup>1</sup>https://arxiv.org/pdf/2306.11073

# Background

•  $\hat{U}_{\Psi}$  is constructed via an operator  $\hat{Q}_{\Psi}$  that performs function evaluation in an ancilla register:

$$\hat{Q}_{\Psi} |j\rangle |0\rangle_a^{\otimes m} = |j\rangle |\Psi'(j)\rangle_a, \qquad (4)$$

with  $\Psi'(j) \equiv \Psi(j)/2\pi$ 

• Currently,  $\hat{Q}_{\Psi}$  is implemented using gate-intensive linear piecewise functions (LPF)

## Background

#### Aim

Implement  $\hat{Q}_{\Psi}$  in a gate-efficient way using a parametrised quantum circuit (PQC)

#### Remark

The n-qubit register containing the  $|j\rangle$  and the m-qubit register containing the  $|\Psi'(j)\rangle$  will be referred to as the input register and target register, respectively.

David Amorim PQC Function Evaluation 2024 5/13

### Approach: a QCNN

- A quantum convolutional neural network (QCNN) is used to tackle the problem
- A QCNN is a parametrised quantum circuit involving multiple layers
- Two types of network layers are implemented:
  - Convolutional layers (CL) involve multi-qubit entanglement gates
  - Input layers (IL)<sup>2</sup> involve controlled single-qubit operations on target qubits
- Input qubits only appear as controls throughout the QCNN

David Amorim PQC Function Evaluation 2024 6 / 13

# Convolutional Layers (CLs)

- Each CL involves the cascaded application of a two-qubit operator on the target register
- A general two-qubit operator involves 15 parameters
- To reduce the parameter space, the three-parameter operator

$$\mathcal{N}(\alpha, \beta, \gamma) = \exp\left(i\left[\alpha X \otimes X + \beta Y \otimes Y + \gamma Z \otimes Z\right]\right) \tag{5}$$

is applied, at the cost of restricting the search space

- This can be decomposed into 3 CX, 3  $R_z$ , and 2  $R_y$  gates
- A two-parameter real version,  $\mathcal{N}_{\mathbb{R}}(\lambda,\mu)$ , can be obtained by removing the  $R_z$

# Convolutional Layers (CLs)

- Two types of convolutional layers are implemented:
  - Neighbour-to-neighbour / linear CLs: the  $\mathcal{N}$  (or  $\mathcal{N}_{\mathbb{R}}$ ) gate is applied to neighbouring target qubits
  - All-to-all /quadratic CLs: the  $\mathcal{N}$  (or  $\mathcal{N}_{\mathbb{R}}$ ) gate is applied to all combinations of target qubits
- The  $\mathcal{N}$ -gate cost of neighbour-to-neighbour (NN) layers is  $\mathcal{O}(m)$  while that of all-to-all (AA) layers is  $\mathcal{O}(m^2)$
- Currently, the QCNN uses alternating linear and quadratic CLs

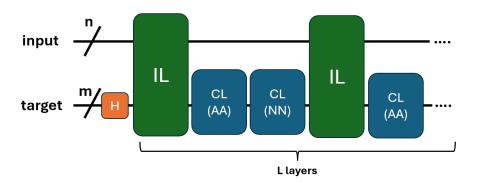

David Amorim PQC Function Evaluation 2024 8/13

# Input Layers (ILs)

- ILs, replacing pooling layers, feed information about the input register into the target register
- An IL involves a sequence of controlled generic single-qubit rotations (CU3 gates) on the target qubits, with input qubits as controls
- For an IL producing states with real amplitudes, the CU3 gates are replaced with  $CR_y$  gates
- Each input qubit controls precisely one CU3 (or  $CR_y$  operation), resulting in an  $\mathcal{O}(n)$  gate cost (no CX gates!)
- ILs are inserted after every second convolutional layer, alternating between control states 0 and 1

David Amorim PQC Function Evaluation 2024 9 / 13

## Summary: QCNN Structure

10 / 13

## Training the QCNN

- For training, the QCNN is wrapped as a SamplerQNN object and connected to PyTorch's Adam optimiser via TorchConnector
- The optimiser determines improved parameter values for each training run (epoch) based on the loss between output and target state
- Beyond loss, mismatch is an important metric:

$$M = 1 - \sqrt{|\langle \psi_{\text{target}} | \psi_{\text{out}} \rangle|}$$
 (6)

- There are two ways to train the QCNN on input data:<sup>4</sup>
  - 1 Training on individual states
  - 2 Training in superposition

David Amorim PQC Function Evaluation 2024 11 / 13

<sup>&</sup>lt;sup>4</sup>Once can also train the QCNN to produce a target distribution independent of the input register, which is equivalent to constructing  $\hat{U}_A$ 

### Training the QCNN

#### 1. Training on Individual States

- One of the  $2^n$  input states,  $|j\rangle$  , is randomly chosen each epoch
- The network is taught to transform  $|j\rangle\,|0\rangle\mapsto|j\rangle\,|\Psi'(j)\rangle$  for each of the states individually

### 2. Training in Superposition

- The same input state is chosen each epoch
- The network is taught to transform

$$\left(\frac{1}{\sqrt{2^n}}\sum_{j=0}^{2^n-1}|j\rangle\right)|0\rangle\mapsto\frac{1}{\sqrt{2^n}}\sum_{j=0}^{2^n-1}|j\rangle\,|\Psi'(j)\rangle\tag{7}$$

• By linearity, this teaches the network to transform  $|j\rangle\,|0\rangle\mapsto|j\rangle\,|\Psi'(j)\rangle$  for each  $|j\rangle$ 

#### Initial Tests

- Initial tests need to be carried out to inform QCNN design choices regarding:
  - a Number of layers
  - **b** Number of epochs
  - **c** Training mode (individually versus in superposition)
  - **d** Use of  $\mathcal N$  and CU3 versus  $\mathcal N_{\mathbb R}$  and  $R_y$
  - Choice of loss function
- The case n=m=2,  $\Psi(x)=x$  (the simplest non-trivial configuration) is an ideal benchmark problem
- Unclear, however, how well these findings extrapolate to more general cases
