# A QCNN for Quantum State Preparation Carnegie Vacation Scholarship

David Amorim

Week 5 (29/07/2024 - 02/08/2024)

1/18

- Preliminaries
- 2 Improving the Loss Function
- Investigating Phase Extraction
- Mitigating Barren Plateaus
- 6 Next Steps

David Amorim QCNN State Preparation 05/08/2024 2 / 18

### Aims for the Week

The following aims were set at the last meeting (29/07/2024):

## Improve Loss Function

Work on an improved version of WILL. Incorporate some phase extraction metrics (e.g.  $\chi$ ,  $\epsilon$ ) into the loss function.

### Investigate Phase Extraction

Study the relationship between mismatch and the extracted phase, i.e. study the operator  $\tilde{Q}^{\dagger}(\hat{I}\otimes\hat{R})\tilde{Q}.$ 

#### Mitigate Barren Plateaus

Work on strategies to mitigate barren plateaus, e.g. implement layer-by-layer training.

#### WILL Revisited

 As discussed at the meeting on 29/07, the definition of WILL (weighted L<sub>p</sub> loss) was amended to:

$$\mathsf{WILL}_{\mathsf{p},\mathsf{q}} = \left(\sum_{k} \left| x_k - y_k \right|^p + |\mathbf{x}_k| \left| [k]_m - \Psi([k]_n) \right|^q \right)^{1/p}, \quad (1)$$

where the changes to the previous definition are highlighted

• Testing this for different  $\Psi$  (with L=6, m=3 and 600 epochs) yielded the following optimal values for p, q:

$\Psi(f)$	p	q
$\phantom{aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa$	0.25	0.5
$\sim f^2$	1	1.5
$\Psi_{H23}$	0.75	2

Table 1: Optimal identified p, q values for WILL

# Comparing SAM, WIM, and WILL

	SAM	WIM	WILL
$\mu$	3.4e-2	6.0e-2	4.5e-1
$\sigma$	1.4e-1	1.1e-1	4.7e-1
$\epsilon$	1.9e-2	9.2e-2	2.6e-1
$\chi$	3.2e-2	5.1e-2	3.7e-1
Ω	4.46	3.19	0.76

Table 2: Comparing loss function metrics for  $\Psi(f)\sim f$  ( $L=6,\ m=3,\ 600$  epochs)

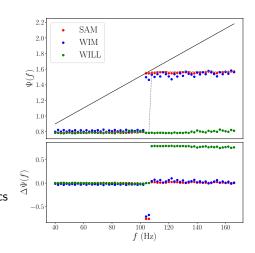

Figure 1: Comparing extracted phase functions for  $\Psi(f) \sim f$  (L=6, m=3, 600 epochs)

# Comparing SAM, WIM, and WILL

	SAM	WIM	WILL
$\mu$	1.9e-1	2.3e-1	6.6e-1
$\sigma$	1.2e-1	1.0e-1	4.1e-1
$\epsilon$	2.2e-1	4.2e-1	2.8e-2
$\chi$	1.9e-1	2.0e-1	6.1e-1
Ω	1.39	1.05	0.57

Table 3: Comparing loss function metrics for  $\Psi(f) \sim f^2$  ( $L=6,\ m=3,\ 600$  epochs)

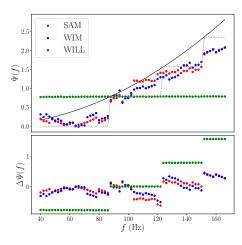

Figure 2: Comparing extracted phase functions for  $\Psi(f)\sim f^2$  ( $L=6,\ m=3,$  600 epochs)

## Other Approaches

- Attempts to define a loss function based directly on  $\hat{Q}^{\dagger}\hat{R}\hat{Q}$ , e.g. minimising  $\chi$ , were unsuccessful
- This is due to the qiskit machine learning environment being build around sampler primitives which return quasi-probabilities instead of probability amplitudes
- Thus, phases cannot be directly taken into account for gradient calculation
- A possible work-around could be to switch to a QCNN based on an estimator primitive, which calculates the expectation value of an observable w.r.t to the state prepared by the network
- This would require the construction of an appropriate operator (note: qiskit supports non-Hermitian observables)

9/18

## An Estimator-based PQC

• Let  $|\tilde{\phi}\rangle$  be the *n*-qubit state produced by the PQC:

$$|\tilde{\phi}\rangle = \sum_{k} \tilde{A}(k)e^{i\tilde{\Psi}(k)}|k\rangle$$
 (2)

The desired output state is

$$|\phi\rangle = \sum_{k} A(k)e^{i\Psi(k)}|k\rangle$$
 (3)

 An estimator-based optimiser calculates the loss and gradients for each epoch based on the expectation value

$$\mathbb{E}(\tilde{\phi}) \equiv \langle \tilde{\phi} | \hat{O} | \tilde{\phi} \rangle = \sum_{k,k'} \tilde{A}(k') \tilde{A}(k) \exp\left(i \left[\tilde{\Psi}(k) - \tilde{\Psi}(k')\right]\right) \langle k' | \hat{O} | k \rangle,$$
(4)

for some operator  $\hat{O}$ 

4 D F 4 D F 4 D F 4 D F 5

## An Estimator-based PQC

• Now construct  $\hat{O}$  such that

$$\langle k'|\hat{O}|k\rangle \equiv \frac{1}{A(k')A(k)} \exp\left(-i\left[\Psi(k) - \Psi(k')\right]\right)$$
 (5)

for  $A(k), A(k') \neq 0$ 

Then

$$\mathbb{E}(\phi) = \sum_{k,k'} 1 = 2^{2n} \tag{6}$$

so that we can train the network to generate  $|\phi\rangle$  by minimising  $|1-\mathbb{E}(\tilde{\phi})/2^{2n}|$ 

- This is highly speculative and computationally very expensive even for simple PQCs due to the way custom operators are handed in qiskit
- Thus, estimator-based PQCs cannot feasibly replace the sampler-based QCNN

#### Loss Function: Conclusion

- The design of the qiskit machine learning library constrains the customisability of loss functions, in particular relating to phases
- Thus, loss functions based directly on the extracted phase factors are (apparently) impossible
- Within the limits of these constraints the best possible loss function seems to be SAM
- Beyond the unsuccessful attempts of WIM and WILL no further ansätze for loss functions come to mind
- For the time being, the search for an improved loss function will be put on hold

# Investigating Phase Extraction

ullet The operator  $\hat{Q}$  is defined via

$$\hat{Q}|j\rangle|0\rangle = |j\rangle|\Psi(j)\rangle \tag{7}$$

- This leaves its action on more general input states  $|j\rangle\,|k\rangle$  (with  $|k\rangle\neq|0\rangle$ ) undetermined
- Thus, there is a family  $\mathcal Q$  of valid implementations of  $\hat Q$  with  $|\mathcal Q|=(n+m)^2-n$
- We can represent a flawed implementation,  $\tilde{Q}$ , of  $\hat{Q}$  via  $\tilde{Q}=\hat{Q}+\lambda\hat{P}$  so that

$$\tilde{Q}\hat{R}\tilde{Q} = \hat{Q}^{\dagger}\hat{R}\hat{Q} + \lambda \left[\hat{Q}^{\dagger}\hat{R}\hat{P} + \hat{P}^{\dagger}\hat{R}\hat{Q}\right] + \lambda^{2} \left[\hat{P}^{\dagger}\hat{R}\hat{P}\right] \tag{8}$$

 Beyond these very general observations no analytical insight into the problem was gained

# Mitigating Barren Plateaus

• The most important strategy to mitigate barren plateaus seems to be a so-called warm start, also known as smart initialisation

GENERATE A FEW PLOTS FOR GRAD AND VAR GRAD FOR DIFFERENT n and m...: diagonose problem: plot var(grad) and —grad—as function of epoch for different n+m (maybe go down with n as well)... most important seems to be 'smart initialisation' or 'warm-start'
